

1 Scope

Running heads are the second source of noise, because they repeat on every page and sit exactly where a heading would. Position alone cannot separate the two: a section title drawn at the top margin looks like a header to any rule that only inspects coordinates. Repetition can, since a header recurs across pages while a title appears once. The benchmark documents in this study were built to exercise those two decisions and nothing else.

Repetition can, since a header recurs across pages while a title appears once. The benchmark documents in this study were built to exercise those two decisions and nothing else. Each document is short, synthetic, and free of copyright, so it can be redistributed with the converter. Hyphenation across a column break is a small case that reveals whether continuation logic inspects the trailing character of a line.

Each document is short, synthetic, and free of copyright, so it can be redistributed with the converter. Hyphenation across a column break is a small case that reveals whether continuation logic inspects the trailing character of a line. A converter that joins lines with a space will emit a broken word at every such break. Tables were drawn with visible ruling lines so that the vector-based detector fires before the text-alignment fallback.

A converter that joins lines with a space will emit a broken word at every such break. Tables were drawn with visible ruling lines so that the vector-based detector fires before the text-alignment fallback. Footnotes were set two points smaller than the body and anchored in the bottom fifth of the column. Their labels are superscript digits, and matching digits appear in the body at the point of reference.

Footnotes were set two points smaller than the body and anchored in the bottom fifth of the column. Their labels are superscript digits, and matching digits appear in the body at the point of reference. The abstract runs across the full measure while the body is set in two columns, which is the arrangement most journals use. The manuscripts we care about in practice are less tidy than this, and we return to them in the discussion.

The manuscripts we care about in practice are less tidy than this, and we return to them in the discussion. The text-layer path handles digital publications; a raster copy of the same file drives the recognition path. Both paths converge on the same block structure before any processor runs.

The text-layer path handles digital publications; a raster copy of the same file drives the recognition path. Both paths converge on the same block structure before any processor runs. Nothing in the pipeline depends on a downloaded model, which is the constraint that motivated the project. Line heights are clustered to recover heading levels when a document has no section numbers.

Nothing in the pipeline depends on a downloaded model, which is the constraint that motivated the project. Line heights are clustered to recover heading levels when a document has no section numbers. When numbers are present they win, because a numbered heading states its own depth. Captions are recognised by their leading label and attached to the nearest figure or table above them.

When numbers are present they win, because a numbered heading states its own depth. Captions are recognised by their leading label and attached to the nearest figure or table above them. Equations are left as images for a later pass rather than transcribed into notation that would be wrong half the time. The remaining processors are direct ports and are documented against the source files they come from.

2 Sample

The scope is deliberately narrow: articles with a text layer, converted for reading by a language model. Within that scope the results are stable across the publishers we tried. Outside it, users should expect to check the output before trusting it. A second reviewer asked for timings; conversion runs at a few pages per second on a laptop.

The sample was drawn from both collections and coded twice^{*}. A second reviewer asked for timings; conversion runs at a few pages per second on a laptop. Most of that time is spent in the table detector, which is invoked on every page. Skipping it on pages with no ruling lines would halve the runtime at no cost to accuracy. We leave that optimisation for a later release and note it here for completeness.

We leave that optimisation for a later release and note it here for completeness. Reading order is the first thing a converter gets wrong and the last thing a reader forgives. The character stream of a well-formed PDF already encodes the order in which the author expected the text to be read. Geometric sorting of blocks discards that signal and replaces it with a guess about columns.

^{*} We thank the editor and two reviewers for their comments on the coding.
