

## **Method and Sample**

Running heads are the second source of noise, because they repeat on every page and sit exactly where a heading would. Position alone cannot separate the two: a section title drawn at the top margin looks like a header to any rule that only inspects coordinates. Repetition can, since a header recurs across pages while a title appears once. The benchmark documents in this study were built to exercise those two decisions and nothing else.

Each document is short, synthetic, and free of copyright, so it can be redistributed with the converter. Hyphenation across a column break is a small case that reveals whether continuation logic inspects the trailing character of a line. A converter that joins lines with a space will emit a broken word at every such break. Tables were drawn with visible ruling lines so that the vector-based detector fires before the text-alignment fallback.

Footnotes were set two points smaller than the body and anchored in the bottom fifth of the column. Their labels are superscript digits, and matching digits appear in the body at the point of reference. The abstract runs across the full measure while the body is set in two columns, which is the arrangement most journals use. The manuscripts we care about in practice are less tidy than this, and we return to them in the discussion.

On two-column pages the guess fails at every figure, every table, and every footnote. Each document is short, synthetic, and free of copyright, so it can be redistributed with the converter.
